Numerical models for forecasting and decisions

Given prior distribution $\mathcal{N}(\mu, C_X)$ on model parameters $x \in \mathbb{R}^{N_x}$ and observations $d^{\mathrm{o}} \in \mathbb{R}^{N_d}$ with forward map $g : \mathbb{R}^{N_x} \to \mathbb{R}^{N_d}$ for unknown x^* and unknown measurement errors $\eta \sim \mathrm{N}(0, C_D)$, i.e.

$$d^{\mathrm{o}} = g(x^*) + \eta$$

we wish to generate samples from the posterior distribution

$$\pi_X(x|d^{\rm o}) = rac{\pi_{XD}(x,d^{\rm o})}{\pi_D(d^{\rm o})} = rac{\exp(-L(x))}{\pi_D(d^{\rm o})}$$

with

$$L(x) = \frac{1}{2} (x - \mu)^T C_X^{-1} (x - \mu) + \frac{1}{2} (g(x) - d^{\circ})^T C_D^{-1} (g(x) - d^{\circ})$$

- Parameters ($N_x \approx 10^5 10^7$) are coefficients of PDEs describing flow and transport.
- Parameters generally modeled as correlated Gaussian
- Observations of the state (e.g. pressure or saturation) spatially sparse or low resolution ($N_d \approx 10^4 10^6$)
- Likelihood function evaluation is expensive (0.1-10 hour)

Metropolized RML

Introduction

Examples 00000000000000 Summary/Challenges

Simple three-layer flow problem¹

- Three parameters $(k_1, k_2, and k_3)$ to be estimated.
- Water injected at constant pressure into all three layers.
- Fluids are produced at constant pressure from all three layers.
- No vertical communication between layers.

< 日 > < 同 > < 日 > < 日 > < 同 > < 日 > < 1 = < の

¹Oliver et al. (2011)

Metropolized RML

Examples 00000000000000 Summary/Challenges

Observations at the outlet face

The total flow rate exhibits a steady decline, but the water cut (fraction of the produced fluid that is water) increases in discrete steps followed by periods of slow continuous increase.

Characterize uncertainty in reservoir predictions, conditional on observations

- Approaches based on 'best solution' and Hessian for uncertainty have not been useful
- Realistic problems are too big for MCMC
- Approximate sampling via 'randomized maximum likelihood' (Oliver et al., 1996; Oliver, 2014) or 'randomize-then-optimize' (Bardsley et al., 2014).

◆□▶ ◆□▶ ◆□▶ ◆□▶ ●□ ��

Metropolized RML

Examples 00000000000000 Summary/Challenges

Generate proposals

The RML method draws samples (x'_i, δ'_i) , i = 1, ..., M, from the Gaussian distribution

$$\begin{aligned} q_{X'\Delta'}(x',\delta') &= c_q \exp\left(-\frac{1}{2}\left(x'-\mu\right)^T C_X^{-1}\left(x'-\mu\right) \\ &-\frac{1}{2}\left(\delta'-d^{\mathrm{o}}\right)^T C_D^{-1}\left(\delta'-d^{\mathrm{o}}\right) \end{aligned}\right) \end{aligned}$$

for given μ and $d^{\rm o}$ and then minimizes the cost functional

$$J_{i}(x) = \frac{1}{2} (x - x_{i}')^{T} C_{X}^{-1} (x - x_{i}') + \frac{1}{2} (g(x) - \delta_{i}')^{T} C_{D}^{-1} (g(x) - \delta_{i}')$$

to determine

$$x_i = \arg \min J_i(x).$$

Metropolized RML

Examples 00000000000000 Summary/Challenges

Proposal density for RML

Minimisation leads to a map from (x', δ') to (x, δ) defined implicitly by

$$x' = x + C_X G^T C_D^{-1}(g(x) - \delta)$$

and

 $\delta' = \delta.$

with transformed distribution $p_{X\Delta}$ given by

$$p_{X\Delta}(x,\delta) := q_{X'\Delta'}(x',\delta') J(x,\delta)$$

= $q_{X'} \left(x + C_X G^T C_D^{-1}(g(x) - \delta) \right) q_{D'}(\delta) J(x,\delta)$

Here $J(x, \delta)$ denotes the determinant of the Jacobian matrix for the inverse map $(x, \delta) \rightarrow (x', \delta')$ and G := Dg(x).

Metropolized RML

Examples 00000000000000 Summary/Challenges

Proposal density for RML

The Jacobian matrix is provided by

$$\left(\begin{array}{cc} I + Db(x,\delta) & -C_X G^{\mathrm{T}} C_D^{-1} \\ 0 & I \end{array}\right)$$

with $b(x, \delta) = C_X G^T C_D^{-1}(g(x) - \delta)$. To simplify we will use

$$V(x) = C_D^{-1} + C_D^{-1} G C_X G^T C_D^{-1}$$

and

$$\eta(x) = -C_D^{-1}(g(x) - d^o) + C_D^{-1}G(x - \mu)$$

= $C_D^{-1}[G(x - \mu) - (g(x) - d^o)]$

Metropolized RML

Examples 00000000000000 Summary/Challenges

Proposal density for RML

After some algebra, we obtain

 $p_{X\Delta}(x,\delta) = \frac{\pi_{X}(x)}{A_{0} \exp\left[-\frac{1}{2}(x-\mu)^{T} C_{X}^{-1}(x-\mu) - \frac{1}{2}(g(x) - d^{o})^{T} C_{D}^{-1}(g(x) - d^{o})\right]} \times A_{1} |V|^{1/2} \exp\left[-\frac{1}{2}(\delta - g(x) - V^{-1}\eta(x))^{T} V(\delta - g(x) - V^{-1}\eta(x))\right]}{\times A_{2} |V|^{-1/2} \exp\left[\frac{1}{2}\eta(x)^{T} V^{-1}\eta(x)\right] J(x,\delta)}$

11/38

Extend the target distribution (Oliver, 2017) Target distribution

$$\pi_X(x) \propto \exp\left[-\frac{1}{2}(x-\mu)^T C_X^{-1}(x-\mu) - \frac{1}{2}(g(x)-d^o)^T C_D^{-1}(g(x)-d^o)
ight].$$

Introduce an extended target distribution

$$\pi_{X\Delta}(x,\delta) \propto \exp\left[-\frac{1}{2}(x-\mu)^T C_X^{-1}(x-\mu) - \frac{1}{2}(g(x)-d^o)^T C_D^{-1}(g(x)-d^o)\right]$$
$$\exp\left[-\frac{1}{2\gamma(1-\gamma)} \left(\delta - g(x) + \gamma(g(x)-d^o)\right)^T \times C_D^{-1}(\delta - g(x) + \gamma(g(x)-d^o))\right].$$

without changing target marginal density for model variable x.

Metropolized RML

Examples 00000000000000 Summary/Challenges

Importance weighting

$$w_i = \frac{\pi_{X\Delta}(x,\delta)}{p_{X\Delta}(x,\delta)}$$

- Could have chosen an extended target to cancel in the case of linear g. Then w_i = 1 for linear.
- Potential problem when the map from (x', δ') to (x, δ) obtained from the condition ΔJ_i = 0 is not one-to-one.

◆□▶ ◆□▶ ◆□▶ ◆□▶ ●□□ ◇◇◇

20/38

Computational effort

- Each proposal required 15 function evaluations using a modified Levenberg-Marquardt and x' to initialize the minimization.
- Computation of the Jacobian of the mapping for MH required an additional 5 function evaluations.
- The acceptance rate for MH is 0.873 so the cost is approximately 23 functions evaluations per independent sample from the target distribution.

Metropolized RML

 Summary/Challenges

Objective function

The objective function along the steepest descent direction for a random starting point.

Summary/Challenges

Paths from prior samples to posterior samples

Yellow regions have significant posterior probability. Red dots are samples from prior distribution. Black curve shows minimization path. Approximately 65% got stuck at local minima.

Summary/Challenges

Rejecting poorly calibrated samples

Objective function:

$$J_i(x) = \frac{1}{2} (x - x_i')^T C_X^{-1} (x - x_i') + \frac{1}{2} (g(x) - \delta_i')^T C_D^{-1} (g(x) - \delta_i')$$

and $x_i = \operatorname{argmin} J_i(x)$.

Model diagnostics³:

$$\hat{J}_i = J_i(x_i)$$

$$\hat{J}_{d} = \frac{1}{2} (g(x_{i}) - \delta')^{T} C_{D}^{-1} (g(x_{i}) - \delta')$$
$$\hat{J}_{d}^{o} = \frac{1}{2} (g(x_{i}) - d^{o})^{T} C_{D}^{-1} (g(x_{i}) - d^{o})$$

Rejecting poorly calibrated samples

<□> <륜> <분> <분> 로는 원일 이익은 29/38

Samples from RML are shown by black dots. True marginal distribution for permeabilities of layers 1 and 2 are shown by contours. Used Levenberg-Marquardt with accurate derivatives for minimization. The joint distribution has six peaks, which were all identified. True model had permeabilities (0.10, 0.15, 0.25.)

Iterative method for sampling via minimization

Solving $\nabla J_i(x) = 0$,

$$\delta x_i^{\ell} = -(x_i^{\ell} - x_i') - C_x G_{\ell}^T \left(C_D + G_{\ell} C_X G_{\ell}^T \right)^{-1} \left(g(x_i^{\ell}) - \delta_i - G_{\ell}(x_i^{\ell} - x_i') \right).$$

where $G_{\ell} = \nabla g(x_i^{\ell})$.

At the first iteration ($\ell=1$), when $x_i^\ell=x_i'$

$$\delta x_i^1 = -C_X G_1^T \Big(C_D + G_1 C_X G_1^T \Big)^{-1} \Big(g(x_i') - \delta_i \Big).$$

31/38

Regularized ensemble-based iterative updating⁴

RML required computation of the Jacobian ${\bf G}$ or the gradient of the objective function. Not easy to get derivatives for reservoir simulators.

Ensemble-based Levenberg-Marquardt iterative updates (iterative ES):

$$\begin{split} \delta \mathbf{x}_{i}^{\ell} &= -\left[\left(\mathbf{1} + \lambda_{\ell} \right) P_{\ell}^{-1} + G_{\ell}^{T} C_{D}^{-1} G_{\ell} \right]^{-1} C_{X}^{-1} (x_{i}^{\ell} - x_{i}') \\ &- \Delta x_{\ell} \Delta d_{\ell}^{T} \left[(\mathbf{1} + \lambda_{\ell}) (N_{e} - 1) C_{D} + \Delta d_{\ell} \Delta d_{\ell}^{T} \right]^{-1} (g(x_{i}^{\ell}) - \delta_{i}) \end{split}$$

where x'_i is the *i*the sample from the prior distribution and Δx_{ℓ} is the matrix of mean removed model variables at the ℓ th iteration.

Regularized ensemble-based iterative updating

- First iteration is exactly the same as would be obtained with the ensemble smoother (except that $C_D \rightarrow (1 + \lambda)C_D$).
- The initial value for λ is typically quite large in reservoir flow problems ($\lambda_1 \sim 10^4$).
- The gradient of the objective function is not modified only the approximation to the Hessian.
- For sampling the posterior, a different objective function is used for each realization.

Minimization for sampling

- Quite robust to nonlinearity (e.g. multimodal posterior distributions)
- Not as robust with respect to prior distribution
- When prior is nongaussian, can sometimes introduce latent Gaussian variables
- The use of ensemble-based methods can increase limitations on uncertainty quantification
- Assumed that the cost function to be minimized was "correct" — will almost certainly be invalidated with sufficient data.
