Informal structure of the study

- Statistical setting: We have (i) data Z^N and (ii) a parameter of interest f. Asymptotics are taken as N → ∞.
- Structure of the problem:

 $\mathcal{H}_N(Z^N) = 0$ for some SDE \mathcal{H}_N , $Z^N \to \xi$ limiting object, $\mathcal{H}(\xi, f) = 0$ for some PDE \mathcal{H} .

• Objective: recover f from the observation of Z^N (or a proxy \mathcal{Z}^N of Z^N).

Paradigmatic examples

1. Cell division: blue growth-fragmentation models

- Age-structured models and the renewal equation
- Size-structured models
- 2. General bifurcating models
- 3. Human population models for demography
 - Cohort effects in human mortality
 - Towards nonlinearity
- 4. Models of interacting neurons \rightsquigarrow Lecture IV
 - Spikes models
 - Hawkes models
- 5. More nonlinear models in a mean-field limit \rightsquigarrow Lecture IV

Motivation: improving mortality estimates

- Mortality table = mortality rates for several age classes (with length one or several years), at several periods in time (usually each year)
- ► Mortality tables ~→ age shape of mortality and dynamics over time

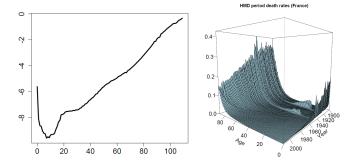

Figure: *Left:* Mortality rate, 2008, France, as a function of age (log-scale).*Right:* Mortality table by age and time

A (very) brief history of demographics

- ► The first mortality table appeared in 1662 by John Graunt ~→ estimation of death probabilities as a function of age.
- 1865: graphical formalizations of life trajectories within a population by Lexis and his contemporaries.

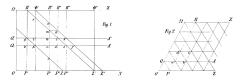

Figure: Examples of the so-called 'Lexis Diagram'

The first demographers understood that it is crucial to (i) keep a non-homogeneous picture and (ii) the measurement of the mortality rate depends on an underlying population dynamics.

Recent awareness about anomalies

Cohort effects have long fascinated demographers.

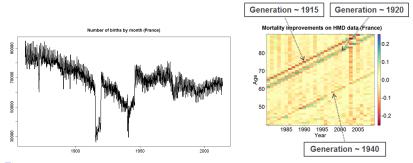

Figure: *Left:* monthly births in France. *Right:* artefact (?) cohort effects in mortality improvements from crude tables of the Human Mortality Database.

 Richards (2008) suggested that cohort effects could be artefacts caused by anomalies in the calculation of death rates due to shocks in birth patterns.

Recent awareness about anomalies

- Cairns et al. (2016) confirm Richards' conclusions with England and Wales data completed on monthly fertility data.
- Boumezoued (2016) aggregates the (HMD) database and the (HFD) database and suggests that these anomalies are universal.

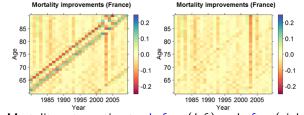

Figure: Mortality rates estimates before (*left*) and after (*right*) correction from Boumezoued (2016).

Example 3: identification of the objects of interest

- ▶ $F, B : \mathbb{R}_+ \times \mathbb{R}_+ \to \mathbb{R}_+$ model parameters.
- ▶ F(t, a): fertility rate of the population with age a at time t.
- ▶ B(t, a): mortality rate of the population with age a at time t.

 Z₀ ∈ M_F: initial age distribution of the population at time t = 0.

Example 3: evolution equation

• $(A_i(t))_{1 \le i \le N_t}$ = all the ages of the population at time *t*.

•
$$Z_t = \sum_{i=1}^{N_t} \delta_{A_i(t)}$$
 with $N_t = \langle Z_t, \mathbf{1} \rangle$.

Associated SDE

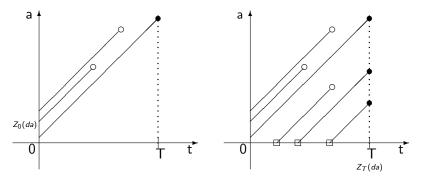

$$Z_{t} = \tau_{t} Z_{0}$$

$$+ \int_{0}^{t} \sum_{i \leq \langle Z_{s-}, 1 \rangle} \int_{0 \leq \theta \leq F(s, a_{i}(Z_{s-}))} \delta_{t-s} Q(ds, di, d\theta)$$

$$- \int_{0}^{t} \sum_{i \leq \langle Z_{s-}, 1 \rangle} \int_{0 \leq \theta \leq B(s, a_{i}(Z_{s-}))} \delta_{a_{i}(Z_{s-})+t-s} \widetilde{Q}(ds, di, d\theta)$$

► Q, \widetilde{Q} independent Poisson random measures, intensity $ds(\sum_{k\geq 1} \delta_k(di)) d\theta$.

Microscopic evolution equation

・ロト ・ 理 ト ・ ヨ ト ・ ヨ ト

э

Figure: Left: Sample path of $Z_0(da)$ and its evolution without births. Right: Sample path of $(Z_t(da), t \in [0, T])$.

Large population limit

- ▶ Large population limit approach: $Z_0 \rightsquigarrow Z_0(N)$, $N \ge 1$, with $\langle Z_0(N), \mathbf{1} \rangle \approx N$.
- N reminiscent of a (large) population size.
- ► Renormalisation: $Z_t \rightsquigarrow Z_t/N =: Z_t^N$ (thus $Z_0^N = N^{-1}Z_0(N)$) yields

$$Z_t^N = \tau_t Z_0^N$$

+ $N^{-1} \int_0^t \sum_{i \le \langle NZ_{s-}^N, 1 \rangle} \int_{0 \le \theta \le F(s, a_i(Z_{s-}^N))} \delta_{t-s}(da) Q(ds, di, d\theta)$
- $N^{-1} \int_0^t \sum_{i \le \langle NZ_{s-}^N, 1 \rangle} \int_{0 \le \theta \le B(s, a_i(Z_{s-}^N))} \delta_{a_i(Z_{s-}^N)+t-s}(da) \widetilde{Q}(ds, di, d\theta).$

Example 3: large population limit

- $N \to \infty$ abstract asymptotic parameter.
- ▶ Reminiscent of a population size : (NZ^N_t, 1) ≈ N for every t ∈ [0, T].
- T is fixed throughout!
- If $Z_0^N \approx g_0(a)da$, then $Z_t^N(da) \approx \xi_t(da) = g(t,a)da$.
- ► g(t, a) weak solution to the McKendrick & Von Foerster equation

$$\begin{cases} \frac{\partial}{\partial t}g(t,a) + \frac{\partial}{\partial a}g(t,a) + B(t,a)g(t,a) = 0, \\ g(0,a) = g_0(a), g(t,0) = \int_{\mathbb{R}_+} F(t,a)g(t,a)da. \end{cases}$$

Example 3: large population limit

We can identify the following objects

- ▶ $N \to \infty$ is arbitrary, reminiscent of the population size $\langle Z_t^N, \mathbf{1} \rangle$ for every $t \in [0, T]$.
- Z^N is $(Z_t^N)_{0 \le t \le T}$ and we observe $\mathcal{Z}^N = Z^N$.
- f is any of the functions $(t, a) \mapsto g(t, a), F(t, a)$ or B(t, a).
- ► \mathcal{H}^N and \mathcal{H} are the SDE and the McKendrick & Von Foerster equation.

Example 3 (Lecture I continued): Human population models

Statistical experiments and methodology

Adaptive nonparametric estimation Nonparametric estimation

From Z^N to a statistical experiment.

- We have a stochastic model (Z_t)_{1≤t≤T}, as a time evolving point measure where either
 - ⟨Z_T, 1⟩ is large when T is large, T deterministic or random (stopping time).
 - *T* is fixed but $Z_t = Z_t^N$ depends on a renormalisation parameter *N* and $\langle Z_t^N, \mathbf{1} \rangle$ is large for every *t* when *N* is large.

- $N \to \infty$ asymptotic parameter.
- We write Z^N for $(Z_t)_{0 \le t \le T(N)}$ or $(Z_t^N)_{0 \le t \le T}$.
- We extract from Z^N an observation \mathcal{Z}^N .

The experiment generated by \mathcal{Z}^N

• \mathcal{Z}^N generates (a sequence of) statistical experiment

$$\left\{\mathbb{P}^{N}_{B,k}, B \in \mathcal{B}, k \in \mathcal{K}\right\}_{N \geq 1}$$

B: parameter of interest, *k* nuisance parameter (possibly known, usually functional).

- ▶ $B : [0,\infty) \times [0,\infty) \rightarrow [0,\infty)$ belongs to a functional class.
- ▶ We need a methodology for recovering *B* non-parametrically.

Nonparametric estimation

- Experiment: $\mathcal{E}^N = \{\mathbb{P}^N_{B,k}, B \in \mathcal{B}, k \in \mathcal{K}\}.$
- Objective: recover B(t, a) with $B \in \mathcal{B}$ from data \mathcal{Z}^N .
- $\widehat{B}^{N}(t,a) = \widehat{B}^{N}(\mathcal{Z}^{N},(t,a))$ estimator of B(t,a).
- Reconstruction criterion

$$\mathcal{R}^{N}(\widehat{B}^{N}(t,a),\mathcal{B}) = \sup_{B \in \mathcal{B}, k \in \mathcal{K}} \mathbb{E}^{N}_{B,k} \big[\big(\widehat{B}^{N}(t,a) - B(t,a) \big)^{2} \big]$$

▶ $v_N \rightarrow 0$ is an admissible rate of of convergence for estimating B(t, a) over \mathcal{B} if there exists $\widehat{B}^N(t, a)$ such that

$$\sup_{N} v_{N}^{-2} \mathcal{R}^{N}(\widehat{B}^{N}(t,a),\mathcal{B}) < \infty.$$

Nonparametric estimation

Sometimes, we only require the (weaker) tightness of

$$\left(v_N^{-1}(\widehat{B}^N(t,a)-B(t,a))\right)_{N\geq 1}$$

uniformly in $B \in \mathcal{B}$, meaning

$$\sup_{B\in\mathcal{B},k\in\mathcal{K}}\mathbb{P}^{N}_{B,k}\big(v_{N}^{-1}\big|\widehat{B}^{N}(t,a)-B(t,a)\big|\geq \mathcal{K}\big)\to 0, \ \, \mathcal{K}\to\infty.$$

• $\widehat{B}_{\star}^{N}(t,a)$ is minimax optimal if

$$\mathcal{R}^{N}(\widehat{B}^{N}(t,a),\mathcal{B}) pprox \inf_{F} \mathcal{R}^{N}(F,\mathcal{B}) \text{ as } N
ightarrow \infty,$$

infimum taken over all estimators F of B(t, a) from \mathcal{Z}^N .

Example 3 (Lecture I continued): Human population models

Statistical experiments and methodology

Adaptive nonparametric estimation Nonparametric estimation

Nonparametric estimation in density estimation

Let us consider an apparently different problem: estimate a probability distribution g(t, a)dtda from a (IID) drawn

$$\mathcal{Z}^N \leftrightarrow (T_1, A_1), \ldots, (T_N, A_N).$$

- Statistical objective: pointwise estimation of g(t, a).
- ▶ Assumption: $g \in L^{\infty}_{loc}$ + local smoothness properties.
- Anisotropic Hölder space $\mathcal{H}^{\alpha,\beta}$:

$$g \in \mathcal{H}^{lpha,eta} \iff \left\{ egin{array}{ll} t \mapsto g(t,a) \in \mathcal{H}^{lpha}, & orall a, \ a \mapsto g(t,a) \in \mathcal{H}^{eta}, & orall t, \end{array}
ight.$$

where \mathcal{H}^{s} is the usual (univariate) Hölder space. $(x \mapsto f(x) \in \mathcal{H}^{s}, s = n + \{s\}, n \text{ integer}, 0 < \{s\} \le 1 \text{ iff}$ $\|f\|_{L^{\infty}} + \sup_{x,y} \frac{|f^{(n)}(y) - f^{(n)}(x)|}{|y - x|^{\{s\}}} < \infty.$

(日)、(型)、(E)、(E)、(E)、(O)への

Preparation: anisotropic estimation

 Kernel reconstruction: Pick a smooth and compactly supported product kernel K

$$K(t,a) = K^{(1)}(t)K^{(2)}(a).$$

• L^1 -normalisation: for $\boldsymbol{h} = (h_1, h_2), h_i > 0$:

$$K_{\mathbf{h}}(t,a) = (h_1h_2)^{-1}K^{(1)}(h_1^{-1}t)K^{(2)}(h_2^{-2}a).$$

Kernel estimation

$$\widehat{g}_{h}^{N}(t,a) = \int_{0}^{T} \int_{\mathbb{R}_{+}} K_{h}(t-s,a-u) \mathcal{Z}^{N}(ds,du).$$

where
$$\mathcal{Z}^N(ds, du) = N^{-1} \sum_{i=1}^N \delta_{(T_i, A_i)}(ds, du)$$
.

Nonparametric estimation in density estimation

- ► Error analysis: standard bias + variance decomposition.
- ► Bias analysis:

$$g_{\boldsymbol{h}}(t,a) = \int_0^T \int_{\mathbb{R}_+} K_{\boldsymbol{h}}(t-s,a-u)g(s,u)duds.$$

• Assume $g \in \mathcal{H}^{\alpha,\beta}$. Then

$$\left|g(t, \mathbf{a}) - g_{\mathbf{h}}(t, \mathbf{a})\right| \lesssim |g|_{\mathcal{H}^{lpha, eta}}(h_1^{lpha \wedge (L+1)} + h_2^{eta \wedge (L+1)})$$

(*L* = order of the kernel: $\int x^{\ell} K(x) dx = \mathbf{1}_{\{\ell=0\}}$ for $\ell = 0, ..., L$.) Remark: different (equivalent) choices for $|g|_{\mathcal{H}^{\alpha,\beta}}$. Nonparametric estimation in density estimation

► Variance analysis:

$$\begin{split} \operatorname{Var}\big(\widehat{g}_{\boldsymbol{N},\boldsymbol{h}}(t,\boldsymbol{a})\big) &\leq N^{-1}\int_{0}^{T}\int_{\mathbb{R}_{+}}K_{\boldsymbol{h}}(t-s,\boldsymbol{a}-u)^{2}g(s,u)dsdu\\ &\leq N^{-1}\|K_{\boldsymbol{h}}\|_{L^{2}}^{2}|g|_{L^{\infty}_{\operatorname{loc}}} = |K|_{2}^{2}|g|_{L^{\infty}_{\operatorname{loc}}}N^{-1}h_{1}^{-1}h_{2}^{-1} \end{split}$$

• Window optimisation $\boldsymbol{h} = \boldsymbol{h}^{\star}$ yields error bound

$$\sup_{g} \mathbb{E} \left[\left(\widehat{g}_{h^{\star}}^{N}(t,a) - g(t,a) \right)^{2} \right] \lesssim N^{-2s(\alpha,\beta)/(2s(\alpha,\beta)+1)}$$

with effective smoothness

$$\frac{1}{s(\alpha,\beta)} = \frac{1}{lpha} + \frac{1}{eta}.$$

Supremum over (local) Hölder balls, minimax optimality.

Towards adaptive estimation

We have established

$$egin{split} \mathbb{E}\Big[ig(\widehat{g}^{N}_{m{h}^{\star}}(t,m{a})-g(t,m{a})ig)^{2}\Big] \lesssimig(m{K}_{m{h}_{1},m{h}_{2}}\star g(t,m{a})-g(t,m{a})ig)^{2}+ig(rac{1}{\sqrt{Nh_{1}h_{2}}}ig)^{2} \ &=:\mathbb{B}_{m{h}}(g)+\mathbb{V}^{N}_{m{h}} \end{split}$$

• Oracle estimation: look for $\boldsymbol{h} = \widehat{h}(\mathcal{Z}^N)$ so that

$$\mathbb{E}\big[\big(\widehat{g}_{\boldsymbol{h}^{\boldsymbol{\mathcal{N}}}}^{\boldsymbol{\mathcal{N}}}(t,\boldsymbol{a})-g(t,\boldsymbol{a})\big)^{2}\big]\lesssim\inf_{\boldsymbol{h}\in\mathcal{H}}\big(\mathbb{B}_{\boldsymbol{h}}(g)+\mathbb{V}_{\boldsymbol{h}}^{\boldsymbol{\mathcal{N}}}\big).$$

- Need H rich enough so that it can mimick the optimal bandwidth h^{*} if g ∈ H^{α,β}.
- ▶ If (α, β) unknown \rightsquigarrow adaptive estimation \rightsquigarrow Lepski's principle.
